## Chapter 3: Decision Tree Learning (part 2)

CS 536: Machine Learning  
Littman (Wu, TA)

### Measuring Entropy

---

- $S$  is a sample of training examples
- $p_{\oplus}$  is the proportion of positive examples in  $S$
- $p_{\otimes}$  is the proportion of negative examples in  $S$

Entropy measures the impurity of  $S$

$$\text{Entropy}(S) = -p_{\oplus} \log p_{\oplus} - p_{\otimes} \log p_{\otimes}$$

## Administration

Questions?

### Entropy Function

---

# Entropy

$Entropy(S)$  = expected number of bits needed to encode class ( $\oplus$  or  $\otimes$ ) of a randomly drawn member of  $S$  (under the optimal, shortest-length code)

Why?

Information theory: optimal length code assigns  $-\log_2 p$  bits to message having probability  $p$ .

So, expected number of bits to encode  $\oplus$  or  $\otimes$  of a random member of  $S$ :

$$p_{\oplus} (-\log p_{\oplus}) + p_{\otimes} (-\log p_{\otimes})$$

# Information Gain

$Gain(S, A)$  = expected reduction in entropy due to sorting  $S$  on  $A$

$Gain(S, A) \equiv$

$$Entropy(S) - \sum_{v \in Values(A)} |S_v|/|S| Entropy(S_v)$$

Here,  $S_v$  is the set of training instances remaining from  $S$  after restricting to those for which attribute  $A$  has value  $v$ .

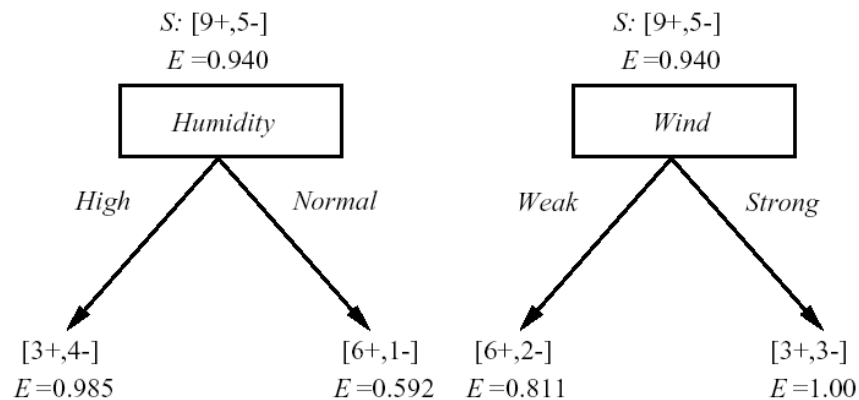

# Which Attribute is Best?

# Training Examples

Day	Outlook	Temp	Hum.	Wind	PlayTennis
D1	Sunny	Hot	High	Weak	No
D2	Sunny	Hot	High	Strong	No
D3	Overcast	Hot	High	Weak	Yes
D4	Rain	Mild	High	Weak	Yes
D5	Rain	Cool	Nml	Weak	Yes
D6	Rain	Cool	Nml	Strong	No
D7	Overcast	Cool	Nml	Strong	Yes
D8	Sunny	Mild	High	Weak	No
D9	Sunny	Cool	Nml	Weak	Yes
D10	Rain	Mild	Nml	Weak	Yes
D11	Sunny	Mild	Nml	Strong	Yes
D12	Overcast	Mild	High	Strong	Yes
D13	Overcast	Hot	Nml	Weak	Yes
D14	Rain	Mild	High	Strong	No

## Selecting the Next Attribute

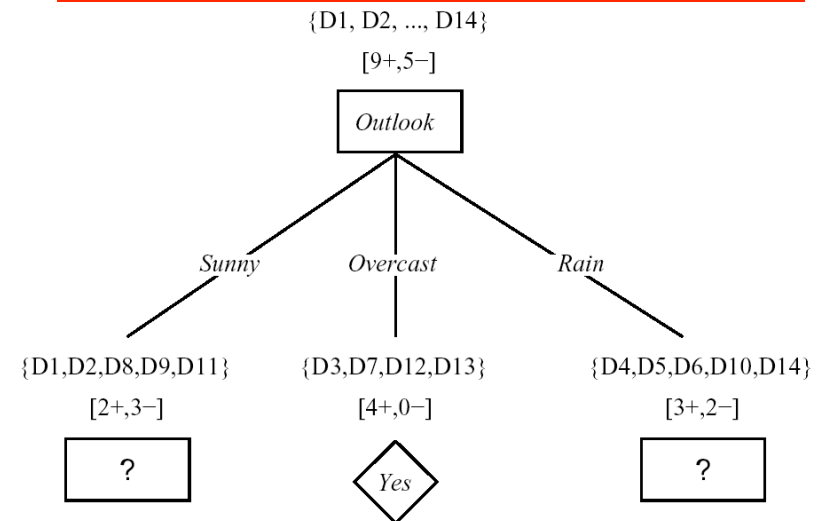

Which attribute is the best classifier?

$$\text{Gain}(S, \text{Humidity}) = .940 - (7/14).985 - (7/14).592 = .151$$

$$\text{Gain}(S, \text{Wind}) = .940 - (8/14).811 - (6/14)1.0 = .048$$

## Attribute Bottom Left?

## Comparing Attributes

$$S_{\text{sunny}} = \{D1, D2, D8, D9, D11\}$$

- $\text{Gain}(S_{\text{sunny}}, \text{Humidity})$   
 $= .970 - (3/5) 0.0 - (2/5) 0.0 = .970$
- $\text{Gain}(S_{\text{sunny}}, \text{Temp})$   
 $= .970 - (2/5) 0.0 - (2/5) 1.0 - (1/5) 0.0 = .570$
- $\text{Gain}(S_{\text{sunny}}, \text{Wind})$   
 $= .970 - (2/5) 1.0 - (3/5) .918 = .019$

## What is ID3 Optimizing?

How would you find a tree that minimizes:

- misclassified examples?
- expected entropy?
- expected number of tests?
- depth of tree given a fixed accuracy?
- etc.?

How decide if one tree beats another?

## Hypothesis Space Search by ID3

---

ID3:

- representation  
: trees
- scoring  
: entropy
- search  
: greedy

## Hypothesis Space Search by ID3

---

- Hypothesis space is complete!
  - Target function surely in there...
- Outputs a single hypothesis (which one?)
  - Can't play 20 questions...
- No back tracking
  - Local minima...
- Statistically-based search choices
  - Robust to noisy data...
- Inductive bias  $\approx$  "prefer shortest tree"

## Inductive Bias in ID3

---

Note  $H$  is the power set of instances  $X$

- Unbiased?
- Not really...
- Preference for short trees, and for those with high information gain attributes near the root
  - Bias is a *preference* for some hypotheses, rather than a *restriction* of hypothesis space  $H$
  - Occam's razor: prefer the shortest hypothesis that fits the data

## Occam's Razor

---

Why prefer short hypotheses?

Argument in favor:

- Fewer short hyps. than long hyps.
  - a short hyp that fits data unlikely to be coincidence
  - a long hyp that fits data might be coincidence

Argument opposed:

- There are many ways to define small sets of hyps
- e.g., all trees with a prime number of nodes that use attributes beginning with "Z"
- What's so special about small sets based on size of hypothesis??

# Overfitting

Consider adding noisy training example #15:  
*Sunny, Hot, Normal, Strong, PlayTennis = No*  
What effect on earlier tree?

# Overfitting

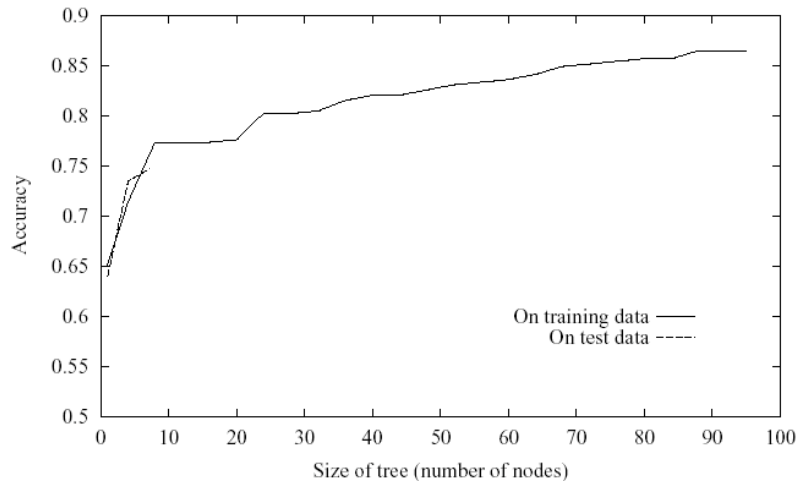

Consider error of hypothesis  $h$  over

- training data:  $error_{train}(h)$
- entire distribution  $D$  of data:  $error_D(h)$

Hypothesis  $h$  in  $H$  **overfits** training data if there is an alternative hypothesis  $h'$  in  $H$  such that

- $error_{train}(h) < error_{train}(h')$ , and
- $error_D(h) > error_D(h')$

# Overfitting in Learning

# Overfitting in Learning

## Avoiding Overfitting

---

How can we avoid overfitting?

- stop growing when data split not statistically significant
- grow full tree, then post-prune (DP alg!)

How to select “best” tree:

- Measure performance over training data
- Measure performance over separate validation data set
- MDL: minimize  
 $size(tree) + size(misclassifications(tree))$

## Reduced-Error Pruning

---

Split data into *training* and *validation* set

Do until further pruning is harmful:

1. Evaluate impact on *validation* set of pruning each possible node (plus those below it)
  2. Greedily remove the one that most improves *validation* set accuracy
- produces smallest version of most accurate subtree
  - What if data is limited?

## Effect of Pruning

---

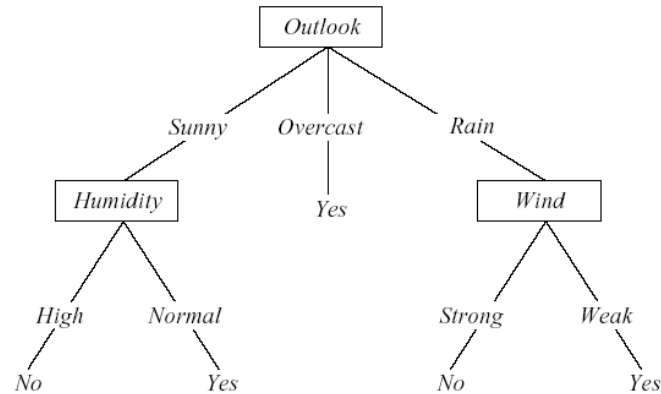

## Rule Post-Pruning

---

1. Convert tree to equivalent set of rules
  2. Prune each rule independently of others
  3. Sort final rules into desired sequence for use
- Perhaps most frequently used method (e.g., C4.5)

## Converting Tree to Rules

---

## The Rules

---

IF (Outlook = Sunny) ^ (Humidity = High)

THEN PlayTennis = No

IF (Outlook = Sunny) ^ (Humidity = Normal)

THEN PlayTennis = Yes

...

## Continuous Valued Attributes

---

Create a discrete attribute to test continuous

- $Temp = 82.5$
- $(Temp > 72.3) = T, F$

Temp:	40	48	60	72	80	90
PlayTennis:	No	No	Yes	Yes	Yes	No

## Attributes with Many Values

---

Problem:

- If one attribute has many values compared to the others, *Gain* will select it
- Imagine using  $Date = Jun\_3\_1996$  as attribute

One approach: use *GainRatio* instead

$$GainRatio(S,A) \equiv Gain(S,A) / SplitInfo(S,A)$$

$$SplitInfo(S,A) \equiv -\sum_{i=1}^c |S_i|/|S| \log_2 |S_i|/|S|$$

where  $S_i$  is subset of  $S$  for which  $A$  has value  $v_i$

## Attributes with Costs

---

Consider

- medical diagnosis, *BloodTest* has cost \$150
- robotics, *Width\_from\_1ft* has cost 23 sec.

How to learn a consistent tree with low expected cost? Find min cost tree.

Another approach: replace gain by

- Tan and Schlimmer (1990)  
 $Gain^2(S,A)/Cost(A)$
- Nunez (1988) [w in [0,1]: importance)  
 $(2^{Gain(S,A)} - 1)/(Cost(A) + 1)^w$

## Unknown Attribute Values

---

Some examples missing values of *A*?

Use training example anyway, sort it

- If node *n* tests *A*, assign most common value of *A* among other examples sorted to node *n*
- assign most common value of *A* among other examples with same target value
- assign probability  $p_i$  to each possible value  $v_i$  of *A* (perhaps as above)
  - assign fraction  $p_i$  of examples to each descendant in tree
- Classify new examples in same fashion
