### Problems with the sockets API

The `sockets` interface forces a read/write mechanism.

Programming is easier with a functional interface.

... but sockets are all we get from the kernel.

### Regular procedure calls

You write:

```c
x = f(a, "test", 5);
```

The compiler parses this and generates code to:

- Push the value 5 on the stack.
- Push the address of the string "test" on the stack.
- Push the current value of `a` on the stack.
- Generate a call to the function `f`.

In compiling `f`, the compiler generates code to:

- Push registers that will be clobbered on the stack to save the values.
- Adjust the stack to make room for local and temporary variables.
- Before a return, unadjust the stack, put the return data in a register, and issue a return instruction.

### Implementing RPC

No architectural support for remote procedure calls.

**Simulate it** with tools we have (local procedure calls).

Simulation makes RPC a language-level construct instead of an operating system construct.

The OS gives us sockets.

The compiler creates code to send messages to invoke remote functions.

The trick

Create **stub functions** to make it appear to the user that the call is local.

On the client side:
- Stub function contains the function's interface.

On the server side:
- Stub function contains the code to get incoming messages, call your local function, and send the results back to the client.

RPC

1984: Birrell & Nelson

Invented a mechanism to call procedures on other machines.

**Remote Procedure Call**

Goal: it should appear to the programmer that a normal call is taking place.

Implementing RPC

No architectural support for remote procedure calls.

**Simulate it** with tools we have (local procedure calls).

Simulation makes RPC a language-level construct instead of an operating system construct.

The OS gives us sockets.

The compiler creates code to send messages to invoke remote functions.

The trick

Create **stub functions** to make it appear to the user that the call is local.

On the client side:
- Stub function contains the function's interface.

On the server side:
- Stub function contains the code to get incoming messages, call your local function, and send the results back to the client.
1. Client calls stub (params on stack)

Client main() &

functions

a=f(x)

client stub

network routines

server

functions

f

2. Stub marshals params to net message

Client main() &

functions

server stub

(skeleton)

a=f(x)

client stub

network routines

server

functions

f

marshaling = placing the parameters in a network buffer

3. Network message sent to server

Client main() &

functions

network routines

client

server

4. Receive message: send it to server stub

Client main() &

functions

network routines

client

server

5. Unmarshal parameters, call server function

Client main() &

functions

f

server stub

(skeleton)

a=f(x)

client stub

network routines

server

functions

f

6. Return from server function

Client main() &

functions

server stub

(skeleton)

a=f(x)

client stub

network routines

server

functions

f
Benefits

- Procedure call interface

- Writing applications is simplified
  - RPC hides all network code into stub functions
  - Application programmers don’t have to worry about details
    - Sockets, port numbers, byte ordering

- Where is RPC in the OSI model?
  - Layer 5: Session layer: Connection management
  - Layer 6: Presentation: Marshaling/data representation
  - Uses the transport layer (4) for communication

RPC has challenges
Parameter passing

Pass by value
- Easy: just copy data to network message

Pass by reference
- Makes no sense without shared memory

Pass by reference?
1. Copy items referenced to message buffer
2. Ship them over
3. Unmarshal data at server
4. Pass local pointer to server stub function
5. Send new values back

To support complex structures
- Copy structure into pointerless representation
- Transmit
- Reconstruct structure with local pointers on server

Representing data

No such thing as incompatibility problems on local system

Remote machine may have:
- Different byte ordering
- Different sizes of integers and other types
- Different floating point representations
- Different character sets
- Alignment requirements

Representing data

IP (headers) forced all to use big endian byte ordering for 16- and 32-bit values

Big endian: Most significant byte in low memory
- SPARC ≤ V9, Motorola 680x0, older PowerPC

Little endian: Most significant byte in low memory
- Intel IA-32, x86

Bi-endian: Processor may operate in either mode
- ARM, PowerPC, MIPS, SPARC V9, IA-64 (Intel Itanium)

main() {
    unsigned int n;
    char *a = (char *)&n;
    n = 0x11223344;
    printf("\02x, \02x, \02x, \02x\n", a[0], a[1], a[2], a[3]);
}

Output on an Intel:
44, 33, 22, 11

Output on a PowerPC:
11, 22, 33, 44

Representing data

Need standard encoding to enable communication between heterogeneous systems
- e.g. Sun’s RPC uses XDR (eXternal Data Representation)
- ASN.1 (ISO Abstract Syntax Notation)
- JSON (JavaScript Object Notation)
- Google Protocol Buffers
- W3C XML Schema Language

Representing data

Implicit typing
- only values are transmitted, not data types or parameter info
- e.g., Sun XDR

Explicit typing
- Type is transmitted with each value
- e.g., ISO’s ASN.1, XML
Binding

A server on each host maintains a DB of *locally* provided services

Client contacts the host on a well-known port to find the port # of the desired server program

Transport protocol

TCP or UDP? Which one should we use?

- Some implementations may offer only one (e.g. TCP)
- Most support several
  - Allow programmer (or end user) to choose at runtime

More issues

Failure
- Local procedure calls do not fail
  - If they core dump, entire process dies
  - More opportunities for error

Performance
- RPC is slower ... a lot slower

Security
- Messages visible over network
- Authenticate client
- Authenticate server

Programming with RPC

Language support
- Most programming languages have no concept of remote procedure calls
  - There are various flavors of RPC
  - Language compilers will not generate client and server stubs

Common solution:
- Use a separate compiler to generate stubs (pre-compiler)

Interface Definition Language & Compiler

- Allow the programmer to specify remote procedure interfaces (names, parameters, return values)
- Pre-compiler can use this to generate client and server stubs:
  - Marshaling code
  - Unmarshaling code
  - Network transport routines
  - Conform to defined interface
- Similar to function prototypes

RPC compiler

IDL --> RPC compiler

- client code (main)
  - client stub
  - headers
  - data conversion
  - compiler

- server functions
  - server skeleton
  - data conversion
  - compiler

client

server
