Java RMI

• RMI = Remote Method Invocation

• Allows a method to be invoked that resides on a different JVM (Java Virtual Machine):
  – Either a remote machine
  – Or same machine, different processes
    • Each process runs on a different Java Virtual Machines (JVM)
    • Different address space per process/JVM

RMI provides object-oriented RPC (Remote Procedure Calls)
Participating processes

• **Client**
  – Process that is invoking a method on a remote object

• **Server**
  – Process that owns the remote object
  – To the server, this is a local object

• **Object Registry (rmiregistry)**
  – Name server that associates objects with names
  – A server registers an object with rmiregistry
  – URL namespace
    - \texttt{rmi://hostname:port/pathname}
    - e.g.: \texttt{rmi://crapper.pk.org:12345/MyServer}

Port number
Classes & Interfaces needed for Java RMI

- **Remote**: for accessing remote methods
  - Used for remote objects

- **Serializable**: for passing parameters to remote methods
  - Used for parameters

- **Also needed**:
  - **RemoteException**: network or RMI errors can occur
  - **UnicastRemoteObject**: used to export a remote object reference or obtain a stub for a remote object
  - **Naming**: methods to interact with the registry
Remote class

- **Remote** class (remote object)
  - Instances can be used remotely
  - Works like any other object locally
  - In other address spaces, object is referenced with an *object handle*
    - The handle identifies the location of the object
  - If a remote object is passed as a parameter, its handle is passed
Serializable interface

- `java.io.Serializable` interface (serializable object)
  - Allows an object to be represented as a sequence of bytes
  - Allows instances of objects to be copied between address spaces
    - Can be passed as a parameter or be a return value to a remote object
    - Value of object is copied (pass by value)
  - Any objects that may be passed as parameters should be defined to implement the `java.io.Serializable` interface
    - **Good news**: you rarely need to implement anything
      - All core Java types already implement the interface
      - For your classes, the interface will serialize each variable iteratively
Remote classes

• Classes that will be accessed remotely have two parts:
  1. interface definition
  2. class definition

• Remote interface
  – This will be the basis for the creation of stub functions
  – Must be public
  – Must extend `java.rmi.Remote`
  – Every method in the interface must declare that it throws `java.rmi.RemoteException`

• Remote class
  – implements Remote interface
  – extends `java.rmi.server.UnicastRemoteObject`
Super-simple example program

- Client invokes a remote method with strings as parameter
- Server returns a string containing the reversed input string and a message
Define the remote interface

SampleInterface.java

```java
import java.rmi.Remote;
import java.rmi.RemoteException;

public interface SampleInterface extends Remote {
    public String invert(String msg) throws RemoteException;
}
```

- Interface is public
- Extends the Remote interface
- Defines methods that will be accessed remotely
  - We have just one method here: `invert`
- Each method must throw a RemoteException
  - In case things go wrong in the remote method invocation
Define the remote class (Sample.java)

```java
import java.rmi.Remote;
import java.rmi.RemoteException;
import java.rmi.server.*;

public class Sample
    extends UnicastRemoteObject
    implements SampleInterface {

    public Sample() throws RemoteException {
    }
    public String invert(String m) throws RemoteException {
        // return input message with characters reversed
        return new StringBuffer(m).reverse().toString();
    }
}
```

- Defines the implementation of the remote methods
- It implements the interface we defined
- It extends the `java.rmi.server.UnicastRemoteObject` class
  - Defines a unicast remote object whose references are valid only while the server process is alive.
Next…

• We now have:
  – The remote interface definition: SampleInterface.java
  – The server-side (remote) class: Sample.java

• Next, we’ll write the server: SampleServer.java

• Two parts:
  1. Create an instance of the remote class
  2. Register it with the name server (rmiregistry)
Server code (SampleServer.java)

- Create the object
  ```java
  new Sample()
  ```

- Register it with the name server (rmiregistry)
  ```java
  Naming.rebind("Sample", new Sample())
  ```

- `rmiregistry` runs on the server
  - The default port is 1099
  - The name is a URL format and can be prefixed with a hostname and port: `//localhost:1099/Server`
import java.rmi.Naming;
import java.rmi.RemoteException;
import java.rmi.server.UnicastRemoteObject;

public class SampleServer {
    public static void main(String args[]) {
        if (args.length != 1) {
            if (args.length != 1) {
                System.err.println("usage: java SampleServer rmi_port");
                System.exit(1);
            }
        }
    }
}
try {
    // first command-line arg: the port of the rmiregistry
    int port = Integer.parseInt(args[0]);

    // create the URL to contact the rmiregistry
    String url = "//localhost:" + port + "/Sample";
    System.out.println("binding " + url);

    // register it with rmiregistry
    Naming.rebind(url, new Sample());
    // Naming.rebind("Sample", new Sample());
    System.out.println("server " + url + " is running...");
    }
    catch (Exception e) {
        System.out.println("Sample server failed:" +
            e.getMessage());
    }
}
Policy file

- When we run the server, we need to specify security policies
- A security policy file specifies what permissions you grant to the program
- This simple one grants all permissions

```java
grant {
    permission java.security.AllPermission;
};
```
The client

- The first two arguments will contain the host & port
- Look up the remote function via the name server
- This gives us a handle to the remote method

```java
SampleInterface sample = (SampleInterface) Naming.lookup(url);

sample.invert(args[i]);
```

- Call the remote method for each argument
- We have to be prepared for exceptions
public class SampleClient {
    public static void main(String args[]) {
        try {
            // basic argument count check
            if (args.length < 3) {
                System.err.println(
                    "usage: java SampleClient rmihost rmiport string... \n");
                System.exit(1);
            }

            // args[0] contains the hostname, args[1] contains the port
            int port = Integer.parseInt(args[1]);
            String url = "/" + args[0] + ":" + port + "/Sample";
            System.out.println("looking up " + url);

            // look up the remote object named “Sample”
            SampleInterface sample = (SampleInterface) Naming.lookup(url);
        }
    }
}
// args[2] onward are the strings we want to reverse
for (int i=2; i < args.length; ++i)

    // call the remote method and print the return
    System.out.println(sample.invert(args[i]));

} catch(Exception e) {
    System.out.println("SampleClient exception: " + e);
}
}
Compile

• Compile the interface and classes:
  javac SampleInterface.java Sample.java
  javac SampleServer.java

• And the client…
  javac SampleClient.java

(you can do it all on one command: javac *.java)

• Note – Java used to use a separate RPC compiler
  – Since Java 1.5, Java supports the dynamic generation of stub classes at runtime
  – In the past, one had to use an RMI compiler, rmic
  – If you want to, you can still use it but it’s not needed
Run

• Start the object registry (in the background):
  \texttt{rmiregistry 12345 \&}
  - An argument overrides the default port 1099

• Start the server (giving it the port of the rmi registry):
  \texttt{java -Djava.security.policy=policy SampleServer 12345}

• Run the client:
  \texttt{java SampleClient svrname 12345 testing abcdefgh}
  - Where svrname is the name of the server host
  - 12345 is the port number of the name server: rmiregistry, not the service!

• See the output:
  \texttt{gnitset}
  \texttt{hgfedcba}
RMI
A bit of the internals
Interfaces

• Interfaces define behavior

• Classes define implementation

• RMI: two classes support the same interface
  – client stub
  – server implementation
Three-layer architecture

- **Stub functions**: Application interaction. Marshaling & unmarshaling
- **Remote reference layer**: Handles the creation & management of remote objects. Deals with the semantics of remote requests (how they behave).
- **Transport layer**: Setting up connections and sending/receiving data
Server - 1

• **Server creates an instance of the server object**
  - extends UnicastRemoteObject
  - TCP socket is bound to an arbitrary port number
  - thread is created which listens for connections on that socket

• **Server registers object**
  - RMI registry is an RMI server (accepts RMI calls)
  - Hands the registry the client stub for that server object
    • contains information needed to call back to the server (hostname, port)
Client - 1

- Client obtains stub from registry
- Client issues a remote method invocation
  - stub class creates a RemoteCall
    - opens socket to the server on port specified in the stub
    - sends RMI header information
  - stub marshals arguments over the network connection
    - uses methods on RemoteCall to obtain a subclass of ObjectOutputStream
    - knows how to deal with objects that extend java.rmi.Remote
      - serializes Java objects over socket
  - stub calls RemoteCall.executeCall()
    - causes the remote method invocation to take place
- Server accepts connection from client
- Creates a new thread to deal with the incoming request
- Reads header information
  - creates RemoteCall to deal with unmarshaling RMI arguments
- **Calls dispatch method of the server-side stub (skeleton)**
  - calls appropriate method on the object
  - sends result to network connection via RemoteCall interface
  - if server threw exception, that is marshaled instead of a return value
• The client unmarshals the return value of the RMI
  – using RemoteCall

• value is returned from the stub back to the client code
  – or an exception is thrown to the client if the return was an exception
The end
