Distributed Systems

Remote Procedure Calls

Problems with sockets

Sockets interface is straightforward

- [connect]
- read/write
- [disconnect]

BUT ... it forces read/write mechanism

- We usually use a procedure call

To make distributed computing look more like centralized:

- I/O is not the way to go

RPC

1984: Birrell & Nelson

- Mechanism to call procedures on other machines

Remote Procedure Call

Goal: it should appear to the programmer that a normal call is taking place

How do <u>regular</u> procedure calls work in programming languages?

Regular procedure calls

Machine instructions for call & return but the compiler really makes the procedure call abstraction work:

- Parameter passing
- Local variables
- Return data

Regular procedure calls

You write:

x = f(a, "test", 5);

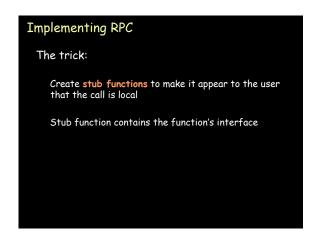

The compiler parses this and generates code to:

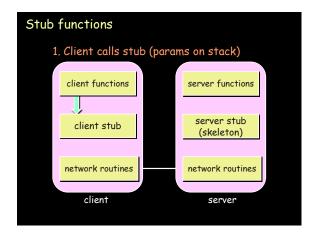

- a. Push the value 5 on the stack
- b. Push the address of the string "test" on the stack
- c. Push the current value of a on the stack
- d. Generate a call to the function f

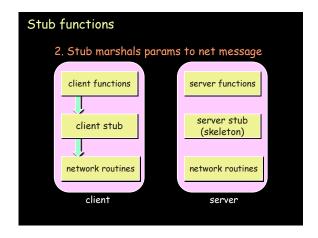

In compiling f, the compiler generates code to:

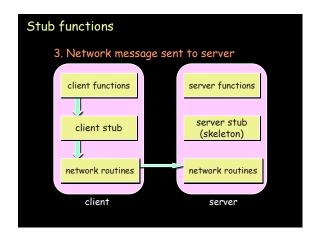

- a. Push registers that will be clobbered on the stack to save the values
- b. Adjust the stack to make room for local and temporary variables
- Before a return, unadjust the stack, put the return data in a register, and issue a return instruction

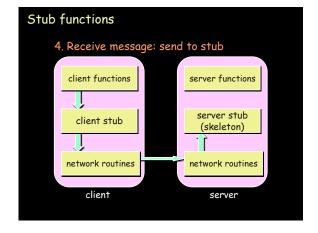

Implementing RPC No architectural support for remote procedure calls Simulate it with tools we have (local procedure calls) Simulation makes RPC a language-level construct instead of an operating system construct

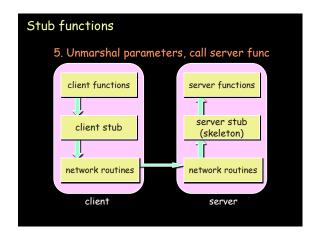

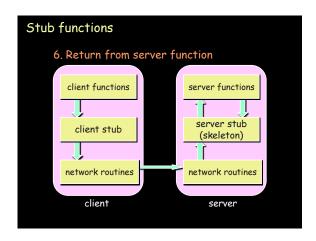

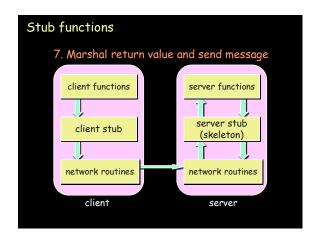

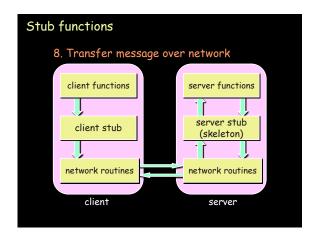

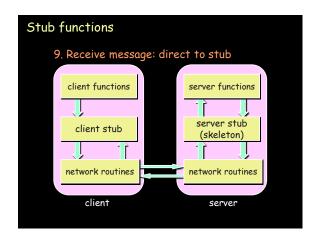

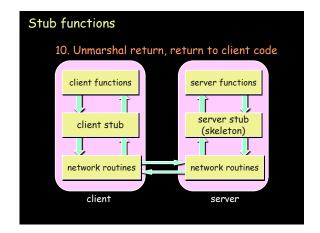

Benefits

- · Procedure call interface
- · Writing applications is simplified
 - RPC hides all network code into stub functions
 - Application programmers don't have to worry about details
 - · Sockets, port numbers, byte ordering
- · RPC: presentation layer in OSI model

RPC has issues

Parameter passing

Pass by value

- Easy: just copy data to network message

Pass by reference

- Makes no sense without shared memory

Pass by reference?

- 1. Copy items referenced to message buffer
- 2. Ship them over
- 3. Unmarshal data at server
- 4. Pass local pointer to server stub function
- 5. Send new values back

To support complex structures

- Copy structure into pointerless representation
- Transmit
- Reconstruct structure with local pointers on server

Representing data

No such thing as

incompatibility problems on local system

Remote machine may have:

- Different byte ordering
- Different sizes of integers and other types
- Different floating point representations
- Different character sets
- Alignment requirements

Representing data

IP (headers) forced all to use big endian byte ordering for 16 and 32 bit values

- Most significant byte in low memory
 - Sparc, 680x0, MIPS, PowerPC G5
 - Intel I-32 (x86/Pentium) use little endian

```
main() {
    unsigned int n;
    char *a = (char *)&n;

    n = 0x11223344;
    printf("%02x, %02x, %02x\n",
        a[0], a[1], a[2], a[3]);
```

Output on a Pentium: 44, 33, 22, 11

Output on a PowerPC: 11, 22, 33, 44

Representing data

Need standard encoding to enable communication between heterogeneous systems

- e.g. Sun's RPC uses XDR (eXternal Data Representation)
- ASN.1 (ISO Abstract Syntax Notation)

Representing data

Implicit typing

- only values are transmitted, not data types or parameter info
- e.g., Sun XDR

Explicit typing

- Type is transmitted with each value
- e.g., ISO's ASN.1, XML

Where to bind?

Need to locate host and correct server process

Where to bind? - Solution 1

Maintain centralized DB that can locate a host that provides a particular service (Birrell & Nelson's 1984 proposal)

Where to bind? - Solution 2

A server on each host maintains a DB of *locally* provided services

Solution 1 is problematic for Sun NFS - identical file servers serve different file systems

Transport protocol

Which one?

- Some implementations may offer only one (e.g. TCP)
- · Most support several
 - Allow programmer (or end user) to choose

When things go wrong

- · Local procedure calls do not fail
 - If they core dump, entire process dies
- More opportunities for error with RPC:
- · Transparency breaks here
 - Applications should be prepared to deal with RPC failure

When things go wrong

- · Semantics of remote procedure calls
 - Local procedure call: exactly once
- · A remote procedure call may be called:
 - O times: server crashed or server process died before executing server code

 - 1 time: everything worked well
 1 or more: excess latency or lost reply from server and client retransmission

RPC semantics

- · Most RPC systems will offer either:
 - at least once semantics
 - or at most once semantics
- Understand application:
 - idempotent functions: may be run any number of times without harm
 - non-idempotent functions: side-effects

More issues

Performance

- RPC is slower ... a lot slower

Security

- messages visible over network
- Authenticate client
- Authenticate server

Programming with RPC

Language support

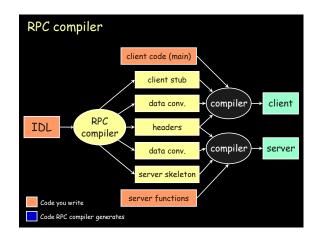

- Most programming languages (C, C++, Java, ...) have no concept of remote procedure calls
- Language compilers will not generate client and server stubs

Common solution:

Use a separate compiler to generate stubs (precompiler)

Interface Definition Language

- Allow programmer to specify remote procedure interfaces (names, parameters, return values)
- · Pre-compiler can use this to generate client and server stubs:
 - Marshaling code
 - Unmarshaling code
 - Network transport routines
 - Conform to defined interface
- · Similar to function prototypes

Writing the program Client code has to be modified - Initialize RPC-related options · Transport type · Locate server/service - Handle failure of remote procedure call Server functions - Generally need little or no modification

RPC API What kind of services does an RPC system need? Name service operations Export/lookup binding information (ports, machines) Support dynamic ports Binding operations Establish client/server communications using appropriate protocol (establish endpoints) Endpoint operations

- Listen for requests, export endpoint to name server

RPC API What kind of services does an RPC system need? Security operations Authenticate client/server Internationalization operations Marshaling/data conversion operations Stub memory management Dealing with "reference" data, temporary buffers Program ID operations Allow applications to access IDs of RPC interfaces
